

WHAT IS CLAIMED IS:

1. A communication device connection method for connecting a call originating terminal to a call terminating terminal via an IP network, comprising:

5 a first step of evaluating communication quality along a route through the IP network from a switching system on an originating side to a switching system on a terminating side when a call originate request has been issued to connect the originating terminal to the
10 terminating terminal via the IP network;

a second step of connecting the originating terminal and the terminating terminal if the communication quality is good; and

if the communication quality is bad, a third step
15 of controlling connection of the communication device in accordance with a command from the caller or controlling connection of the communication device by selecting a route other than the first-mentioned route automatically in accordance with a determination made by a switching
20 system.

2. The method according to claim 1, wherein said first step includes the steps of:

sending a test packet from the switching system on the originating side to the switching system on the
25 terminating side via the route through the IP network before a channel is established;

sending an ACK packet from the switching system on the terminating side to the switching system on the

originating side in response to receipt of the test packet;

measuring, at the switching system on the originating side, delay time from sending of the test
5 packet to receipt of the ACK packet; and

determining whether communication quality is good or bad based upon a comparison of length of the delay time and length of a set time.

SUB A1
10 3. The method according to claim 2, wherein said first step further includes the steps of:

setting beforehand, in conformity with the system, whether the determination as to whether communication quality is good or bad is to be performed every call or every several calls;

15 if the determination is to be performed every several calls, storing results of evaluation of communication quality every several calls; and

performing the determination as to whether communication quality is good or bad with regard to a
20 new call by referring to the results of evaluation of communication quality that have been stored.

4. The method according to claim 2, wherein said first step further includes the steps of:

25 setting beforehand, in conformity with the system, capacity of a single test packet and test-packet transmission count;

accumulating delay time with regard to each test packet; and

determining whether communication quality is good or bad based upon a comparison of an average value of accumulated delay time and length of a set time.

5 5. The method according to claim 1, wherein said first step further includes the steps of:

 preserving communication-quality data such as packet loss rate that prevailed during a call after the call ends; and

10 determining whether communication quality is good or bad by referring to the communication-quality data that has been preserved.

6. The method according to claim 5, wherein the communication-quality data is preserved for every route and for every day of the week and time period.

15 7. The method according to claim 5, wherein the communication-quality data is accumulated for every route and whether communication quality is good or bad is determined by referring to a value obtained by statistically processing the communication-quality data
20 that has been accumulated.

8. The method according to claim 1, wherein in a case where connection of the communication device is controlled in accordance with a command from the caller, the fact that communication quality is bad is output by
25 voice from the originating terminal to so notify the caller.

9. The method according to claim 1, wherein in a case where connection of the communication device is

controlled in accordance with a command from the caller,
one of the following control operations is instructed by
a command from the user: (1) connection control via the
above-mentioned route; (2) connection control via an
5 alternative route through the IP network; (3) connection
control through another route via a network other than
the IP network; and (4) transmission disconnect control.

10. The method according to claim 1, wherein in a case
where connection of the communication device is
10 controlled in accordance with a determination made by
the switching system, the system selects an alternative
route through the IP network or another route within a
network other than the IP network and connects the
originating terminal and the terminating terminal via
15 the route selected.

11. The method according to claim 1, wherein said third
step further includes the steps of:

establishing beforehand by agreement with a
subscriber, if communication quality is bad, whether (1)
20 connection of the communication device is to be
controlled in accordance with a command from the caller
or (2) connection of the communication device is to be
controlled by selecting a route automatically in
accordance with a determination made by the system; and
25 controlling connection of the communication device
based upon the agreement with the subscriber if the
communication quality is bad.

12. A communication device connection apparatus for

connecting a call originating terminal to a call terminating terminal via an IP network, comprising:

Quality evaluation means for evaluating communication quality along a route through the IP network from a switching system on an originating side to a switching system on a terminating side when a call originate request has been issued to connect the originating terminal to the terminating terminal via the IP network;

10 means for connecting the originating terminal and the terminating terminal if the communication quality is good;

means for controlling connection of the communication device in accordance with a command from the caller, and/or means for controlling connection of the communication device by selecting a route other than the first-mentioned route automatically without relying upon a command from the caller, if the communication quality is bad.

20 13. The apparatus according to claim 12, wherein said quality evaluation means includes:

means for sending a test packet from the switching system on the originating side to the switching system on the terminating side via the route through the IP network before a channel is established;

means for receiving an ACK packet sent from the switching system on the terminating side in response to receipt of the test packet and measuring delay time from

sending of the test packet to receipt of the ACK packet;
and

means for whether communication quality is good or
bad based upon a comparison of length of the delay time
5 and length of a set time.

SUPA! 14. The apparatus according to claim 13, wherein
said quality evaluation means includes:

means for setting beforehand whether the
determination as to whether communication quality is
10 good or bad is to be performed every call or every
several calls; and

means for storing results of evaluation of
communication quality every several calls if the
determination is to be performed every several calls;

15 said quality evaluation means performing the
determination as to whether communication quality is
good or bad with regard to a new call by referring to
the results of evaluation of communication quality that
have been stored.

20 15. The apparatus according to claim 13, wherein said
quality evaluation means further includes:

means for setting beforehand capacity of a single
test packet and test-packet transmission count; and

means for accumulating delay time with regard to
25 each test packet;

said quality evaluation means determining whether
communication quality is good or bad based upon a
comparison of a value obtained by statistically

processing delay time that has been accumulated and a set time.

16. The apparatus according to claim 12, wherein said quality evaluation means further includes:

5 preservation means for preserving communication-quality data such as packet loss rate that prevailed during a call after the call ends; and

 means for determining whether communication quality is good or bad by referring to the communication-quality
10 data that has been preserved.

17. The apparatus according to claim 16, wherein the communication-quality data is preserved for every route and for every day of the week and time period.

18. The apparatus according to claim 16, wherein the
15 communication-quality data is accumulated in said preservation means for every route, and said quality evaluation means determines whether communication quality is good or bad by referring to a value obtained by statistically processing the communication-quality
20 data that has been accumulated.

19. The apparatus according to claim 12, wherein said means for controlling connection of the communication device in accordance with a command from the caller includes notification means for outputting, by voice,
25 the fact that communication quality is bad to so notify the caller.

20. The apparatus according to claim 12, wherein said means for controlling connection of the communication

device in accordance with a command from the caller performs one of the following control operations in response to a command from the caller: (1) connection control via the above-mentioned route; (2) connection
5 control via an alternative route through the IP network; (3) connection control through another route via a network other than the IP network; and (4) transmission disconnect control.

21. The apparatus according to claim 12, further
10 comprising means for establishing beforehand by agreement with a subscriber, if communication quality is bad, whether (1) connection of the telephone is to be controlled in accordance with a command from the caller or (2) connection of the communication device is to be
15 controlled by selecting a route automatically in accordance with a determination made by the system.
